- What is an AI Job Exposure Index?
 - A quantitative measure aimed at determining how much the labor force in a specific country or region is exposed to AI
 - It is a projection exercise aimed at understanding what proportion of jobs could be potentially exposed to AI in the future
 - Important implications
 1. Determine policy focus priorities
 2. Identify important gaps in research

- Study Objective: Produce an AI job exposure index for countries of South-West Asia and North Africa Region
- Methodological contribution in the global south context
 - Different rates of technological adoption
 - Infrastructure readiness, legal and bureaucratic obstacles to adoption
 - Variation in nature of work between developing and industrialized economies
 - Data scarcity

- We adopt a skills-based approach
 - Define an occupation as a combination of skills that can be performed by human capabilities
- The exposure index is then constructed through a recursive process
 1. Skill exposure index
 2. Occupation exposure index
 3. Labor force exposure index

- A survey is designed to estimate skills exposure index
 - A sample of regional experts in AI development, use, and integration identified by our research team
 - Expand base sample through snowball sampling
 - Survey is conducted online
- Survey participants are asked to determine the likelihood that 9 AI abilities are able to replicate human task performance capabilities

Canada

- Challenges and Limitations
 - Sample representativeness
 - Length of survey (9 AI abilities x 52 human skills)
- ⇒ Low rate of participation, sample composition could be driven by the original set of participants
- Experts could be over optimistic about AI capabilities and adoption

Canada 

- Participants are asked to respond to a random subset of sections of the online survey
 - Demographic questions section
 - 2 sections focusing on the impact of an AI ability replicate human skills (2 x 52 questions)
- Adopt a different scale: instead of the Yes/No we use a more nuanced scale: Fully capable, partly capable, barely capable, not capable

Canada

- Defining an occupation as a combination of skills
 - Use online job posting to identify frequency of keywords that could be associated with the 52 skills
 - Construct a taskshare of skills for every occupation (country specific/regional)
- Main challenge: Selective job posting
 - Variation in usage of online job posting by country, sector of employment and occupation levels

- Labor force survey will then be used to determine occupation share in the labor force
- Using these labor share we can construct labor force AI exposure index
- Not all countries have publicly available and recent labor force surveys
- This approach identify employment exposure based on current composition of labor force and does not account for potential structural changes in anticipation

Canada

- Correcting for infrastructure readiness and willingness to adopt the new technology
 - Experts likely focus on technological feasibility
 - They might account for infrastructural limitations
 - Likely overstate adoption willingness and economic feasibility
- Adoption in many sectors is a political economy question rather than technological feasibility
- Additional layer of correction through FGDs

- What can we do with this index?
 - Distributional analysis of job exposure. Based on occupational exposure who are the most exposed groups (gender, age groups, migrant workers, educational levels, sectors, etc)
 - Identify key vulnerabilities and areas of exposure to identify important research avenues for policy interventions
